

CONNECT. GROW. FIGHT TOGETHER.

The Greencubes delivery.

What has shipped, and what is next.

A record of what Miraj Mor's team at Greencubes has built on Bridge, prepared so Dillon can present it accurately in Miraj's place. It covers the account and verification work, the security behind it, what a visitor can see today, and exactly what is built, what is merged, and what is live.

Prepared

September 3, 2026

CoversMilestone 3, Accounts and
Verification**Status**Functionally complete, pending
merge

Greencubes has built a secure, working backend. It is not merged, and it is not live yet.

Miraj Mor's team at Greencubes has delivered a genuinely secure Bridge backend: real server side role checks, a correct allowlist of which addresses may even talk to it, and, as of today, the one missing piece of the puzzle that had been blocking cookie based sign in. Paired with the account creation screen Greencubes built by adopting Momentum's reference design, the first two steps of the four step Join flow now work end to end against the real backend on a review build. Steps 3 and 4, the organization details and the verification review, are still ahead of us: they need backend work that has not started and a product decision that only Melissa and Tori can make. The branch carrying all of this, pull request 16, is complete and clear to merge, but it has not been merged, so none of it is visible to a real visitor yet.

LINES LEFT TO FIX BEFORE
THAT BRANCH IS READY TO
MERGE

What to say with confidence

- The backend now sends the header that lets a secure cookie session work at all
- Both the session check and the identity check correctly refuse an unproven visitor
- Greencubes folded its sign in work into the one shared contract Momentum's frontend already uses, instead of running a second, separate path
- Step 1 of Join, the twelve role grid, and the new Step 2, account creation, both run against the real backend on the review address today
- The branch is reviewed as mergeable; nothing is fighting it technically

What to be careful not to say

- That any of this is live. It is not, until the branch merges
- That Steps 3 and 4 are built. No screens exist for them yet
- That the client has approved Steps 2 and 4. That decision is still open
- That Miraj's own account of cookies, logout, and tests is independently reconfirmed end to end. Some of it is; the rest is his report, stated as his report

The one line to remember

Greencubes fixed the exact thing that was broken, on time, and the fix is good. What is left is a small cleanup, a merge, and a decision that belongs to Melissa and Tori rather than to either engineering team.

Steps 2 to 4 are the heart of this delivery. Here is what each one does.

Joining Bridge is a four step sequence. Step 1, choosing a role from twelve options, has been live in production for some time. Steps 2 to 4, covered below, are where this round of work concentrated: a real account, a real organization record, and a real verification review.

STEP	WHAT IT CAPTURES	WHAT THE BACKEND MUST PROVIDE	STATUS
Step 1 of 4 <i>/join</i>	The member's role, chosen from a grid of twelve. Each role shows its own next step requirements and a founding member pricing note.	Nothing new. This step has always run on its own.	LIVE IN PRODUCTION
Step 2 of 4 <i>/join/account</i>	Account creation: display name, email, password, and confirmation. Shows the role chosen in Step 1 with a link back to change it.	Registration and sign in that return a working session. Delivered today, header and all.	BUILT, PENDING MERGE
Step 3 of 4 <i>no route yet</i>	Organization details: legal name, public name, EIN, license, location, and a named contact owner.	A way to save a partly filled organization record against the member's account between visits. Not started.	AWAITING BACKEND AND APPROVAL
Step 4 of 4 <i>no route yet</i>	Verification evidence and review submission: uploading documents, a safe summary of what was submitted, and a case an admin can decide on.	Secure upload handling, document scanning, and a verification case record. Not started.	AWAITING BACKEND AND APPROVAL

Why Step 2 counts as a real milestone

Step 2 is not a mock screen. On the review build it posts to Greencubes' own backend, gets a real answer back, and the resulting session is what carries a member into their profile. That is the difference between a screen that looks finished and a screen that is finished.

Why Steps 3 and 4 are not close, technically

There is nowhere for the data to go yet. Saving an organization's draft, accepting a document upload, and opening a verification case are all backend capabilities that have not been started. Building the screens before that exists would mean another mock, which is the opposite of what this round of work was trying to fix.

What is concretely built, and the one decision that is not an engineering problem.

What pull request 16 concretely does

- Removes the file that had been writing a sign in token into the browser's own storage. There is nowhere left in the browser for that proof to sit
- Removes the second, separate sign in client Greencubes had added, folding registration, sign in, and sign out into the one shared contract every other Bridge screen already calls
- Keeps the setting that tells the browser to send its cookie along with each request, which a cookie session depends on
- Restores the twelve role grid as Step 1 exactly as it was, and gives account creation its own Step 2 address
- Touches 38 files across the frontend, reviewed and marked clear to merge

What still has to happen before Steps 3 and 4 can be built

- Greencubes has to build the organization draft, the upload, and the verification case capabilities described on the previous page
- Melissa and Tori have to decide what evidence each of the twelve roles must actually submit
- Melissa and Tori also have to decide what the public "Verified" badge is promising to someone who sees it on a profile
- Only once both of those land does building Steps 3 and 4 become a normal engineering task rather than a guess

Do not represent Steps 2 and 4 as client approved

This has been stated plainly to the whole team, in writing, since the end of August: Step 2 and Step 4 product approval is still with Melissa and Tori, and those screens should not be represented as client approved. That instruction still stands today, and it is the reason Steps 3 and 4 are described here as awaiting a decision rather than awaiting a schedule.

Where to see Steps 1 and 2 today

Both run against the real backend right now on Greencubes' own review address, detailed in the next section. That address is not the one the client normally uses, and nothing on it is visible to a real visitor until the branch merges.

The part nobody sees, that everything else depends on.

Greencubes built the piece of Bridge that decides who is allowed to do what. Three things about it stand out, and all three were checked directly today rather than taken on trust.

The server says no by default

A request with no proof of login, and a request carrying a faked one, are both refused by the two most important checks: the session check and the "who is this" check. Checked directly against the live backend today, both return the correct refusal every time.

Only Bridge's own addresses get an answer

The backend keeps a list of exactly which Bridge web addresses are allowed to ask it anything. An address that is not on that list gets nothing back. This is what stops another website from quietly borrowing a Bridge member's session.

Cookie sessions versus a token in the browser

A cookie session means the server hands the browser a small, locked box that only the server can open again to prove it is really you. A token stored in the browser means that proof sits out in the open on the device itself, which is far easier for a stray, malicious bit of code on the page to find and copy.

That is why the fix matters. As of today, the backend sends the header that allows the locked box approach to work at all, and Greencubes removed the file that had been leaving a copy of the proof sitting in the browser's storage. Less sits exposed on the visitor's device than did a day ago.

What Miraj reports, stated as his report

Dillon has independently confirmed the header above and the two correct refusals. The rest of this list is Greencubes' own account, current as of September 2 and 3, and has not yet been reconfirmed against a live signed in session: sign in issues a secure cookie the page's own scripts cannot read, the credentialed cross origin rule works end to end, the session check authenticates through that cookie, a fallback token method still works for other callers, signing out clears the cookie and revokes the session on the server, a session check right after signing out correctly comes back unauthenticated, every admin and member only address is protected on the server rather than only hidden on the screen, and Greencubes' own tests pass.

A working preview, built from Greencubes' own branch and the real backend.

Every address below was checked directly today on Greencubes' review build, which is the one place this work can currently be shown. It is not the client's normal address, and nothing on it is visible to a real visitor until the branch merges.

ADDRESS	RESULT	WHAT IT SHOWS
/ (home)	200	The real backend is compiled into this build, not a stand in.
/login	200	The sign in screen Greencubes built, wired to the real backend.
/join	200	Step 1, the twelve role grid, restored and unchanged.
/join/account	200	Step 2, account creation, built by Greencubes on Momentum's screen design.
/my-profile	200	Where a signed in member lands.
/admin/dashboard	200	The administrator workspace Greencubes built.
/admin	404	The short address alone does not yet forward to the dashboard. A small fix, not built yet.

What the demo can show today

A visitor can pick a role, create an account against the real backend, sign in, sign out, and reach both the member profile and the administrator workspace. That is a genuine, working slice of Bridge, not a script.

What the demo cannot show

There is nothing to click through for organization details or for submitting verification evidence. Those screens do not exist yet, for the reasons on the previous page. Typing the short admin address on its own currently lands on a not found page rather than the dashboard.

One caution for the room

This review build is reachable only by its own specific address, tied to Greencubes' branch. If it is shown in the meeting, it should be introduced as a preview of work still pending merge, not as the site the client already has a link to.

Short, accurate answers to the five questions most likely to come up.

Is it live?

No. It works today on Greencubes' own preview address, with the real backend behind it. The production address the client normally uses still runs the older build until that branch is reviewed and merged.

Is it secure?

The parts that are built are secure by the measures that matter most, and those were checked directly today: the server refuses a request with no login proof or a faked one, and only Bridge's own addresses can reach it at all. Sign in now uses a cookie that the page's own scripts cannot read, according to Greencubes, which closes the gap a browser stored token leaves open.

When can we launch this piece?

The remaining engineering is small: four lines across three files still point at the wrong repository and need correcting, then the branch needs a review and a merge. The larger open item is not an engineering task. It is a decision only Melissa and Tori can make, on what evidence each role must submit and what the "Verified" badge promises.

What is left?

Fix the stale repository reference, merge the branch, add the one redirect so the short admin address works, and independently reconfirm Greencubes' cookie and session claims once real sign ins are possible. Then build Steps 3 and 4 once the client decision above is made and the backend can save an organization's draft and accept evidence.

Who owns what?

Greencubes owns the merge readiness and the backend work Steps 3 and 4 still need. Momentum owns the admin redirect, the independent recheck, and building Steps 3 and 4 once approved. Melissa and Tori own the evidence and badge decision. Each item below has one named owner.

Built, merged, live, and accepted are four different words. Keep them apart.

The single most common way a status update becomes inaccurate is trading one of these four words for another. This page exists so nobody in the room has to reach for the right one on the spot.

SAY THIS

NOT THAT

Steps 1 and 2 are built and working on the review address.

Steps 1 and 2 are live.

Pull request 16 is complete and clear to merge.

Pull request 16 is merged.

The backend now sends the header that cookie sessions need.

Sign in is completely done.

Steps 3 and 4 are designed, and are waiting on backend work and a client decision.

Steps 3 and 4 are built.

Greencubes delivered a secure backend for what has been built so far.

The backend is entirely finished.

Miraj reports the cookie and logout behavior works end to end.

Dillon has confirmed the cookie and logout behavior works end to end.

A quick way to check any sentence before saying it

Built means the code exists and passes its checks on a branch. **Merged** means that branch has joined the shared branch everyone deploys from. **Live** means a real visitor can reach it today. **Accepted** means the client has said yes to it, in writing, with a date. All four can be true of the same feature at completely different times, and today, for this work, only the first is true.

Every remaining item, with exactly one owner each.

GREENCUBES

The branch and the backend

- Correct the four lines across three files that still point at the wrong repository
- Get pull request 16 reviewed and merged into the shared branch
- Build the organization draft, upload, and verification case work that Steps 3 and 4 need

MOMENTUM, DILLON

Frontend and verification

- Add the redirect so the short admin address lands on the dashboard instead of a not found page
- Independently reconfirm Miraj's cookie, session, and logout claims once real sign ins are possible, rather than relying on his report alone
- Build Steps 3 and 4 once the backend work and the client decision below both land

CLIENT, MELISSA AND TORI

The one decision that blocks the rest

- Decide what verification evidence each of the twelve roles must actually supply
- Decide what the public "Verified" badge is promising to someone who sees it

The single most useful thing that can happen this week

A dated answer from Melissa and Tori on the evidence and badge questions above. Everything else outstanding is a normal engineering task with a known owner. That one is not, and it is the only item genuinely holding Steps 3 and 4 back from starting.

Eight terms, in plain language.

Cookie session

A sign in method where the server hands the browser a small, secure file that proves who is signed in, instead of the browser holding the proof itself.

Bearer token

A sign in credential the browser stores and sends itself. More convenient for some code, more exposed if a script on the page is ever compromised.

Server side role check

A permission check the backend itself enforces, so a member cannot see or do more than their role allows even if the screen is tricked.

Preview build

A working copy of the site anyone with the link can open, built from one specific branch, used for review before anything reaches real visitors.

HttpOnly

A setting on that secure file that keeps the page's own scripts from ever reading it, so a malicious script cannot steal it.

Allowlist of origins

The backend's list of exactly which Bridge web addresses may ask it for anything at all. Anyone else gets no answer.

Merged versus live

Merged means the code has joined the shared branch. Live means a real visitor can reach it. A branch can be finished and still be neither.

Verification case

Bridge's internal record of a member's submitted evidence and its review status, from submission through an admin's decision.
